Extra, Extra - Read All About It: Nearly All Binary Searches and Mergesorts are Broken

Friday, June 2, 2006

Posted by Joshua Bloch, Software Engineer

Note: Computing the average in the right way is not trivial, see [On finding the average of two unsigned integers without overflow](#)

related operations: ceiling division, rounding division

## Potentially Catastrophic Failure

$$51 \text{ days} = 51 \cdot 24 \cdot 60 \cdot 60 \cdot 1000 = 4\,406\,400\,000 \text{ ms}$$

---

Boeing 787s must be turned off and on every 51 days to prevent ‘misleading data’ being shown to pilots

# C++ Data Model

C++ Data Model	OS	Number of Bits					
		short	int	long	long long	pointer	
ILP32	Windows/Unix 32-bit	16	32	32	64	32	
LLP64	Windows 64-bit	16	32	<u>32</u>	64	64	
LP64	Linux 64-bit	16	32	<u>64</u>	64	64	

`char` is always 1 byte

**LP32:** Windows 16-bit APIs (no more used)

```
int*_t <cstdint>
```

C++11 provides fixed width integer types.

They have the same size on any architecture:

```
int8_t, uint8_t
```

```
int16_t, uint16_t
```

```
int32_t, uint32_t
```

```
int64_t, uint64_t
```

*Good practice:* Prefer fixed-width integers instead of native types. `int` and `unsigned` can be directly used as they are widely accepted by C++ data models

`int*_t` types are not “real” types, they are merely *typedefs* to appropriate fundamental types

C++ standard does not ensure a one-to-one mapping:

- There are **five** distinct *fundamental types* (`char`, `short`, `int`, `long`, `long long`)
- There are **four** `int*_t` *overloads* (`int8_t`, `int16_t`, `int32_t`, and `int64_t`)

Warning: I/O Stream interprets `uint8_t` and `int8_t` as `char` and not as integer values

```
int8_t var;  
cin >> var; // read '2'  
cout << var; // print '2'  
int a = var * 2;  
cout << a; // print '100' !!
```

## `size_t`

`size_t <cstddef>`

`size_t` ↗ is an *alias* data type capable of storing the biggest representable value on the current architecture

- `size_t` is an unsigned integer type (of at least 16-bit)
- `size_t` is the return type of `sizeof()` and commonly used to represent size measures
- `size_t` is 4 bytes on 32-bit architectures, and 8 bytes on 64-bit architectures
- C++23 adds `uz` / `UZ` literals for `size_t`, e.g. `5uz`

## ptrdiff\_t ★

### ptrdiff\_t <cstddef>

`ptrdiff_t` is an *alias* data type used to store the results of the difference between pointers or iterators

- `ptrdiff_t` is the signed version of `size_t` commonly used for computing pointer differences
- `ptrdiff_t` are 4 bytes on 32-bit architectures, and 8 bytes on 64-bit architectures
- C++23 adds `z / Z` for `ptrdiff_t`, e.g. `5z`

`uintptr_t *`

`uintptr_t <cstdint>`

`uintptr_t` (C++11) is an integer type that can be converted from and to a  
void pointer

- `uintptr_t` is an unsigned type
- `sizeof(uintptr_t) == sizeof(void*)`
- `uintptr_t` is an *optional* type of the standard and compilers may not provide it

# Arithmetic Operation Semantics

**Overflow** The result of an arithmetic operation exceeds the word length, namely the largest positive/negative values

**Wraparound** The result of an arithmetic operation is reduced modulo  $2^N$  where  $N$  is the number of bits of the word

**Saturation** The result of an arithmetic operation is constrained within a fixed range defined by a minimum and maximum value. If the result of an operation exceeds this range, it is “*clamped*” to the boundary value

## Signed/Unsigned Integer Characteristics

Without undefined behavior, ***signed*** and ***unsigned*** integers use the same exact hardware, and they are equivalent at binary level thanks to the two-complement representation

```
#include <cstdint>
int      a1 = INT_MAX;
int      b1 = a1 + 4; // 100000000000000000000000000000011

unsigned a2 = INT_MAX;
unsigned b2 = a2 + 4; // 100000000000000000000000000000011
```

However, ***signed*** and ***unsigned*** integers have different semantics in C++. The compiler can exploit undefined behavior to optimize the code even if such operations are well-defined at hardware level

## Signed Integer

- ❑ Represent positive, negative, and zero values ( $\mathbb{Z}$ )
- ❑ *Properties:* Commutative, reflexive, not associative (overflow/underflow)
- ✓ Represent the human intuition of numbers
- ✓ All bitwise operations are well-defined, except shift

## Signed Integer - Problems

- ⚠ More negative values ( $2^{31} - 1$ ) than positive ( $2^{31} - 2$ )

Even multiply, division, and modulo by -1 can fail, e.g. `INT_MIN * -1`

- ⚠ *Overflow/underflow semantic* → undefined behavior

Possible behavior: *overflow*:  $(2^{31} - 1) + 1 \rightarrow min$ ,    *underflow*:  $-2^{31} - 1 \rightarrow max$

- ⚠ Shift could lead to undefined behavior `x << y`

- undefined behavior if `y` is larger than the number of bits of `x`
- implementation-defined if `x` is negative (until C++20)
- undefined behavior if `y` is negative

## Unsigned Integer

- Represent only *non-negative* values ( $\mathbb{N}$ )
- *Properties:* commutative, reflexive, associative
- Discontinuity in 0,  $2^{32} - 1$
- ✓ Wraparound semantic  $\rightarrow$  well-defined (modulo  $2^{32}$ )
- ✓ Bit-wise operations are well-defined, except shift
  - ⚠ Shift could lead to undefined behavior  $x \ll y$ 
    - undefined behavior if  $y$  is larger than the number of bits of  $x$

## Google Style Guide

Because of historical accident, the C++ standard also uses unsigned integers to represent the size of containers - many members of the standards body believe this to be a mistake, but it is effectively impossible to fix at this point

**Solution:** use `int64_t`

**max value:**  $2^{63} - 1 = 9,223,372,036,854,775,807$  or

9 quintillion (9 billion of billion),  
about 292 years in nanoseconds,  
9 million terabytes

*When use signed integer?*

- if it can be mixed with negative values, e.g. subtracting byte sizes
- prefer expressing non-negative values with signed integer and assertions
- optimization purposes, e.g. exploit undefined behavior for overflow or in loops

*When use unsigned integer?*

- if the quantity can never be mixed with negative values (?)
- bitmask values
- optimization purposes, e.g. division, modulo
- safety-critical system, signed integer overflow could be “non-deterministic”

---

Subscripts and sizes should be signed, *Bjarne Stroustrup*

Don't add to the signed/unsigned mess, *Bjarne Stroustrup*

Integer Type Selection in C++: in Safe, Secure and Correct Code, *Robert C. Seacord*

# Arithmetic Type Limits

Query properties of arithmetic types in C++11:

```
#include <limits>

std::numeric_limits<int>::max()           // 231 - 1
std::numeric_limits<uint16_t>::max()        // 65,535

std::numeric_limits<int>::min()           // -231
std::numeric_limits<unsigned>::min()        // 0
```

\* this syntax will be explained in the next lectures

# Promotion and Truncation

**Promotion** to a larger type keeps the sign

```
int16_t x = -1;  
int      y = x; // sign extend  
cout << y;      // print -1
```

**Truncation** to a smaller type is implemented as a modulo operation with respect to the number of bits of the smaller type

```
int      x = 65537; // 2^16 + 1  
int16_t y = x;      // x % 2^16  
cout << y;          // print 1  
  
int      z = 32769; // 2^15 + 1 (does not fit in a int16_t)  
int16_t w = z;      // (int16_t) (x % 2^16 = 32769)  
cout << w;          // print -32767
```

# Mixing Signed/Unsigned Errors

1/3

```
unsigned a = 10; // array is small
int      b = -1;
array[10ull + a * b] = 0; // ?
```

💀 Segmentation fault!

```
int f(int a, unsigned b, int* array) { // array is small
    if (a > b)
        return array[a - b]; // ?
    return 0;
}
```

💀 Segmentation fault for `a < 0` !

```
// v.size() return unsigned
for (size_t i = 0; i < v.size() - 1; i++)
    array[i] = 3; // ?
```

💀 Segmentation fault for `v.size() == 0` !

# Mixing Signed/Unsigned Errors

Easy case:

```
unsigned x = 32;      // x can be also a pointer
x          += 2u - 4; // 2u - 4 = 2 + (2^32 - 4)
                  //           = 2^32 - 2
                  // (32 + (2^32 - 2)) % 2^32
cout << x;          // print 30 (as expected)
```

What about the following code?

```
uint64_t x = 32;      // x can be also a pointer
x          += 2u - 4;
cout << x;
```

## A real-world case:

```
// allocate a zero rtx vector of N elements
//
// sizeof(struct rtvec_def) == 16
// sizeof(rtunion) == 8
rtvec rtvec_alloca(int n) {
    rtvec rt;
    int i;
    rt = (rtvec)obstack_alloc(
        rtl_obstack,
        sizeof(struct rtvec_def) + ((n - 1) * sizeof(rtunion)));
// ...
    return rt;
}
```

The C++ standard does not prescribe any specific behavior (undefined behavior) for several integer/unsigned arithmetic operations

- *Signed integer overflow/underflow*

```
int x = std::numeric_limits<int>::max() + 20;
```

- *More negative values than positive*

```
int x = std::numeric_limits<int>::max() * -1; // (2^31 -1) * -1
cout << x;                                // -2^31 +1 ok
```

```
int y = std::numeric_limits<int>::min() * -1; // -2^31 * -1
cout << y; // hard to see in complex examples // 2^31 overflow!!
```

- Initialize an integer with a value larger than its range is undefined behavior

```
int z = 3000000000; // undefined behavior!!
```

- Bitwise operations on signed integer types with negative value is undefined behavior

```
int y = -1 << 12;    // undefined behavior!!, until C++20
int z = 1 << -12;    // undefined behavior!!
```

- Shift larger than #bits of the data type is undefined behavior even for `unsigned`

```
unsigned y = 1u << 32u; // undefined behavior!!
```

- Undefined behavior in implicit conversion

```
uint16_t a = 65535; // 0xFFFF
uint16_t b = 65535; // 0xFFFF
cout << (a * b);   // print '-131071' undefined behavior!! (int overflow)
```

expected: 4'294'836'225

# Undefined Behavior - Signed Overflow Example 1

3/7

```
#include <climits>
#include <cstdio>

void f(int* ptr, int pos) {
    pos++;
    if (pos < 0)      // <-- the compiler could assume that signed overflow never
        return;        //      happen and "simplify" the condition to check
    ptr[pos] = 0;
}

int main() {                      // the code compiled with optimizations, e.g. -O3
    int* tmp = new int[10];        // leads to segmentation faults with clang, while
    f(tmp, INT_MAX);             // it terminates correctly with gcc
    printf("%d\n", tmp[0]);
}
```

s/open.c of the Linux kernel

```
int do_fallocate(..., loff_t offset, loff_t len) {
    inode *inode = ...;
    if (offset < 0 || len <= 0)
        return -EINVAL;
    /* Check for wrap through zero too */
    if ((offset + len > inode->i_sb->s_maxbytes) || (offset + len < 0))
        return -EFBIG;      // the compiler is able to infer that both 'offset' and
    ...                      // 'len' are non-negative and can eliminate this check,
}                                // without verify integer overflow
```

src/backend/utils/adt/int8.c of PostgreSQL

```
if (arg2 == 0) {
    ereport(ERROR, (errcode(ERRCODE_DIVISION_BY_ZERO), // the compiler is not aware
                   errmsg("division by zero")));           // that this function
}                                               // doesn't return
/* No overflow is possible */
PG_RETURN_INT32((int32) arg1 / arg2); // the compiler assumes that the divisor is
                                     // non-zero and can move this statement on
                                     // the top (always executed)
```

Even worse example:

```
#include <iostream>

int main() {
    for (int i = 0; i < 4; ++i)
        std::cout << i * 1000000000 << std::endl;
}

// with optimizations, it is an infinite loop
// --> 1000000000 * i > INT_MAX
// undefined behavior!!

// the compiler translates the multiplication constant into an addition
```

---

Why does this loop produce undefined behavior?

Is the following loop safe?

```
void f(int size) {  
    for (int i = 0; i < size; i += 2)  
        ...  
}
```

- What happens if `size` is equal to `INT_MAX` ?
- How to make the previous loop safe?
- `i >= 0 && i < size` is not the solution because of *undefined behavior* of signed overflow
- Can we generalize the solution when the increment is `i += step` ?

## Overflow / Underflow

Detecting wraparound for unsigned integral types is **not trivial**

```
// some examples

bool is_add_overflow(unsigned a, unsigned b) {
    return (a + b) < a || (a + b) < b;
}

bool is_mul_overflow(unsigned a, unsigned b) {
    unsigned x = a * b;
    return a != 0 && (x / a) != b;
}
```

Detecting overflow/underflow for signed integral types is even harder and must be checked before performing the operation

## Saturation Arithmetic ★

C++26 adds four main functions to perform **saturation arithmetic** with integer types in the `<numeric>` library. In other words, the undefined behavior or the wrap-around behavior for overflow/underflow is replaced by **saturation** values, namely the *minimum* or *maximum* values of the operands

- `T add_sat(T x, T y)`
- `T sub_sat(T x, T y)`
- `T mul_sat(T x, T y)`
- `T div_sat(T x, T y)`
- `R saturate_cast<R>(T x)`

# Floating-point Types and Arithmetic

---

# IEEE Floating-Point Standard

**IEEE754** is the technical standard for floating-point arithmetic

The standard defines the binary format, operations behavior, rounding rules, exception handling, etc.

*First Release* : 1985

*Second Release* : 2008. Add 16-bit, 128-bit, 256-bit floating-point types

*Third Release* : 2019. Specify min/max behavior

see The IEEE Standard 754: One for the History Books

IEEE754 technical document:

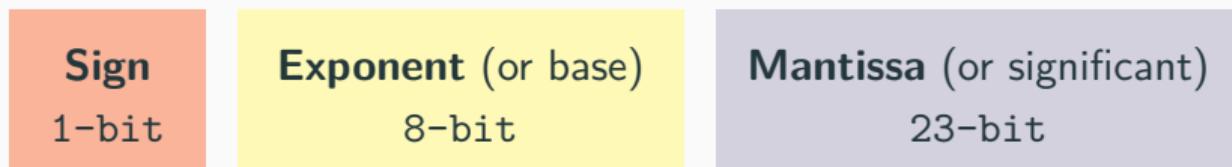

754-2019 - IEEE Standard for Floating-Point Arithmetic

In general, **C/C++ adopts IEEE754 floating-point standard:**

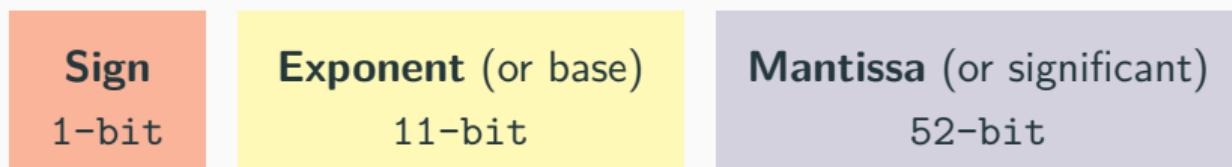

[en.cppreference.com/w/cpp/types/numeric\\_limits/is\\_iec559](https://en.cppreference.com/w/cpp/types/numeric_limits/is_iec559)

# 32/64-bit Floating-Point

- IEEE754 Single-precision (32-bit) float

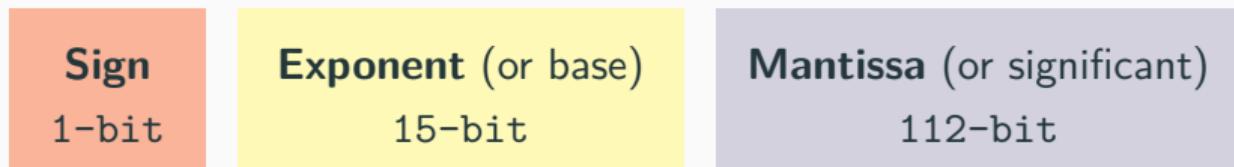

- IEEE754 Double-precision (64-bit) double

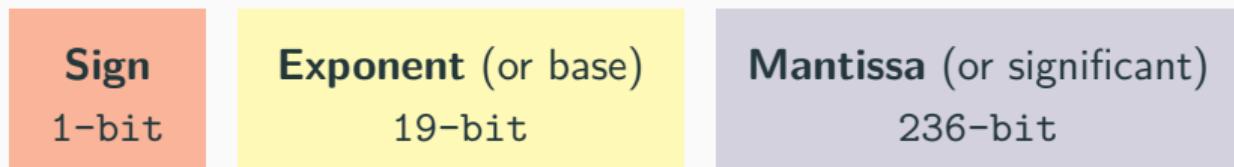

# 128/256-bit Floating-Point

- IEEE754 Quad-Precision (128-bit) `std::float128_t` C++23

- IEEE754 Octuple-Precision (256-bit) (not standardized in C++)

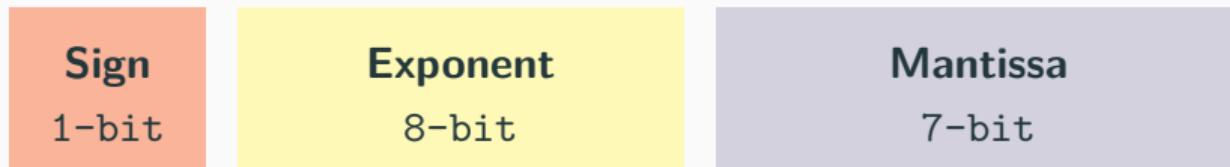

# 16-bit Floating-Point

- IEEE754 16-bit Floating-point ( `std::binary16_t` ) C++23 → GPU, Arm7

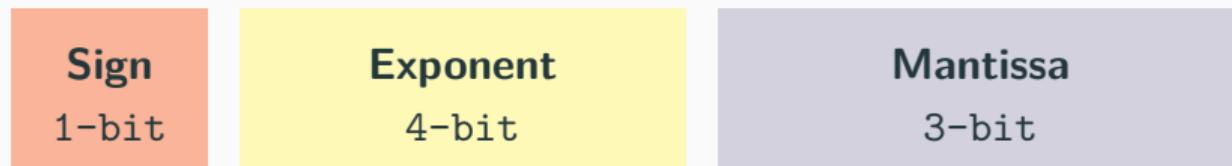

- Google 16-bit Floating-point ( `std::bfloat16_t` ) C++23 → TPU, GPU, Arm8

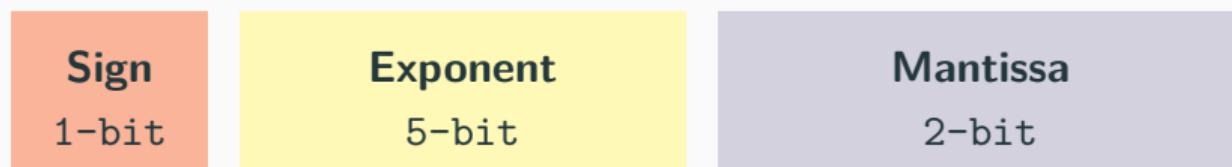

# 8-bit Floating-Point (Non-Standardized in C++/IEEE)

- E4M3

- E5M2

- 
- Floating Point Formats for Machine Learning, *IEEE draft*
  - FP8 Formats for Deep Learning, *Intel, Nvidia, Arm*

- **TensorFloat-32 (TF32)** Specialized floating-point format for deep learning applications
- **Posit** (John Gustafson, 2017), also called *unum III (universal number)*, represents floating-point values with *variable-width* of exponent and mantissa.  
It is implemented in experimental platforms

- 
- NVIDIA Hopper Architecture In-Depth
  - Beating Floating Point at its Own Game: Posit Arithmetic
  - Posits, a New Kind of Number, Improves the Math of AI
  - Comparing posit and IEEE-754 hardware cost

- **Microscaling Formats (MX)** Specification for low-precision floating-point formats defined by AMD, Arm, Intel, Meta, Microsoft, NVIDIA, and Qualcomm.  
It includes FP8, FP6, FP4, (MX)INT8
- **Fixed-point** representation has a fixed number of digits after the radix point (decimal point). The gaps between adjacent numbers are always equal. The range of their values is significantly limited compared to floating-point numbers.  
It is widely used on embedded systems

## Floating-point number:

- *Radix* (or base):  $\beta$
- *Precision* (or digits):  $p$
- *Exponent* (magnitude):  $e$
- *Mantissa*:  $M$

$$n = \underbrace{M}_p \times \beta^e \quad \rightarrow \quad \text{IEEE754: } 1.M \times 2^e$$

```
float f1 = 1.3f;    // 1.3
float f2 = 1.1e2f; // 1.1 · 102
float f3 = 3.7E4f; // 3.7 · 104
float f4 = .3f;    // 0.3
double d1 = 1.3;   // without "f"
double d2 = 5E3;   // 5 · 103
```

## Exponent Bias

In IEEE754 floating point numbers, the exponent value is offset from the actual value by the **exponent bias**

- The exponent is stored as an unsigned value suitable for comparison
- Floating point values are lexicographic ordered
- For a single-precision number, the exponent is stored in the range [1, 254] (0 and 255 have special meanings), and is biased by subtracting 127 to get an exponent value in the range [-126, +127]

0  
+

$$10000111 \\ 2^{(135-127)} = 2^8$$

$$11000000000000000000000000000000 \\ \frac{1}{2^1} + \frac{1}{2^2} = 0.5 + 0.25 = 0.75 \xrightarrow{\text{normal}} 1.75$$

$$+1.75 * 2^8 = 448.0$$

## Normal number

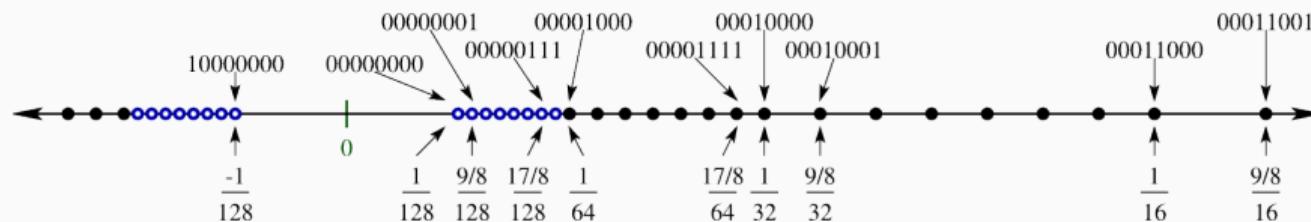

A **normal** number is a floating point value that can be represented with *at least one bit set in the exponent* or the mantissa has all 0s

## Denormal number

**Denormal** (or subnormal) numbers fill the underflow gap around zero in floating-point arithmetic. Any non-zero number with magnitude smaller than the smallest normal number is denormal

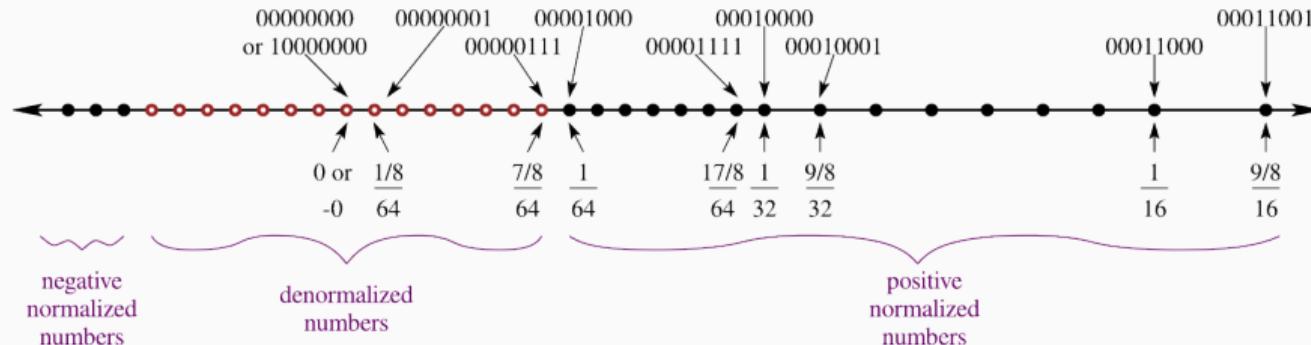

A **denormal** number is a floating point value that can be represented with *all 0s in the exponent*, but the mantissa is non-zero

Why denormal numbers make sense:

(↓ normal numbers)

The problem: distance values from zero

(↓ denormal numbers)

## Infinity

In the IEEE754 standard, `inf` (infinity value) is a numeric data type value that exceeds the maximum (or minimum) representable value

Operations generating `inf`:

- $\pm\infty \cdot \pm\infty$
- $\pm\infty \cdot \pm\text{finite\_value}$
- $\text{finite\_value } op \text{ finite\_value} > \text{max\_value}$
- $\text{finite value} / \pm 0$

There is a single representation for `+inf` and `-inf`

Comparison: `(inf == finite_value)`  $\rightarrow$  false

`(±inf == ±inf)`  $\rightarrow$  true

```
cout << 5.0 / 0.0;      // print "inf"
cout << -5.0 / 0.0;     // print "-inf"

auto inf = std::numeric_limits<float>::infinity;
cout << (-0.0 == 0.0);           // true, 0 == 0
cout << ((5.0f / inf) == ((-5.0f / inf))); // true, 0 == 0
cout << (10e40f) == (10e40f + 9999999.0f); // true, inf == inf
cout << (10e40) == (10e40f + 9999999.0f); // false, 10e40 != inf
```

## NaN

In the IEEE754 standard, NaN (not a number) is a numeric data type value representing an undefined or non-representable value

Floating-point operations generating **NaN** :

- Operations with a NaN as at least one operand
- $\pm\infty \cdot \mp\infty$ ,  $0 \cdot \infty$
- $0/0, \infty/\infty$
- $\sqrt{x}$ ,  $\log(x)$  for  $x < 0$
- $\sin^{-1}(x), \cos^{-1}(x)$  for  $x < -1$  or  $x > 1$

Comparison:  $(\text{NaN} == x) \rightarrow \text{false}$ , for every  $x$

$(\text{NaN} == \text{NaN}) \rightarrow \text{false}$

There are many representations for NaN (e.g.  $2^{24} - 2$  for float)

The specific (bitwise) NaN value returned by an operation is implementation/compiler specific

```
cout << 0 / 0;           // undefined behavior
cout << 0.0 / 0.0;       // print "nan" or "-nan"
```

# Machine Epsilon

## Machine epsilon

**Machine epsilon**  $\epsilon$  (or *machine accuracy*) is defined to be the smallest number that can be added to 1.0 to give a number other than one

IEEE 754 Single precision :  $\epsilon = 2^{-23} \approx 1.19209 * 10^{-7}$

IEEE 754 Double precision :  $\epsilon = 2^{-52} \approx 2.22045 * 10^{-16}$

# Units at the Last Place (ULP)

## ULP

**Units at the Last Place** is the gap between consecutive floating-point numbers

$$ULP(p, e) = \beta^{e-(p-1)} \rightarrow 2^{e-(p-1)}$$

Example:

$$\beta = 10, p = 3$$

$$\pi = 3.1415926\ldots \rightarrow x = 3.14 \times 10^0$$

$$ULP(3, 0) = 10^{-2} = 0.01$$

Relation with  $\varepsilon$ :

- $\varepsilon = ULP(p, 0)$
- $ULP_x = \varepsilon * \beta^{e(x)}$

## Floating-Point Representation of a Real Number

The machine floating-point representation  $\text{fl}(x)$  of a *real number*  $x$  is expressed as

$$\text{fl}(x) = x(1 + \delta), \text{ where } \delta \text{ is a small constant}$$

The approximation of a *real number*  $x$  has the following properties:

**Absolute Error:**  $|\text{fl}(x) - x| \leq \frac{1}{2} \cdot ULP_x$

**Relative Error:**  $\left| \frac{\text{fl}(x) - x}{x} \right| \leq \frac{1}{2} \cdot \epsilon$

- NaN (mantissa  $\neq 0$ )

*	11111111	*****

## Floating-point - Limits

```
#include <limits>
// T: float or double

std::numeric_limits<T>::max()           // largest value

std::numeric_limits<T>::lowest()        // lowest value (C++11)

std::numeric_limits<T>::min()           // smallest value

std::numeric_limits<T>::denorm_min()   // smallest (denormal) value

std::numeric_limits<T>::epsilon()       // epsilon value

std::numeric_limits<T>::infinity()     // infinity

std::numeric_limits<T>::quiet_NaN()    // NaN
```

## Floating-point - Useful Functions

```
#include <cmath> // C++11

bool std::isnan(T value)          // check if value is NaN
bool std::isinf(T value)          // check if value is ±infinity
bool std::isfinite(T value)        // check if value is not NaN
                                    // and not ±infinity

bool std::isnormal(T value); // check if value is Normal

T     std::ldexp(T x, p)      // exponent shift  $x * 2^p$ 
int   std::ilogb(T value)       // extracts the exponent of value
```

Floating-point operations are written

- $\oplus$  addition
- $\ominus$  subtraction
- $\otimes$  multiplication
- $\oslash$  division

$$\odot \in \{\oplus, \ominus, \otimes, \oslash\}$$

$op \in \{+, -, *, /\}$  denotes exact precision operations

(P1) In general,  $a \text{ op } b \neq a \odot b$

(P2) **Not Reflexive**  $a \neq a$

- *Reflexive without NaN*

(P3) **Not Commutative**  $a \odot b \neq b \odot a$

- *Commutative without NaN ( $\text{NaN} \neq \text{NaN}$ )*

(P4) In general, **Not Associative**  $(a \odot b) \odot c \neq a \odot (b \odot c)$

- even excluding NaN and inf in intermediate computations

(P5) In general, **Not Distributive**  $(a \oplus b) \otimes c \neq (a \otimes c) \oplus (b \otimes c)$

- even excluding NaN and inf in intermediate computations

**(P6) Identity on operations is not ensured**

- $(a \ominus b) \oplus b \neq a$
- $(a \oslash b) \otimes b \neq a$

**(P7) Overflow/Underflow** Floating-point has “saturation” values inf, -inf

- as opposite to integer arithmetic with wrap-around behavior

# Special Values Behavior

## Zero behavior

- $a \odot 0 = \text{inf}$ ,  $a \in \{\text{finite} - 0\}$  [IEEE-764], undefined behavior in C++
- $0 \odot 0, \text{inf} \odot 0 = \text{NaN}$  [IEEE-764], undefined behavior in C++
- $0 \otimes \text{inf} = \text{NaN}$
- $+0 = -0$  but they have a different binary representation

## Inf behavior

- $\text{inf} \odot a = \text{inf}$ ,  $a \in \{\text{finite} - 0\}$
- $\text{inf} \oplus \otimes \text{inf} = \text{inf}$
- $\text{inf} \ominus \text{inf} = \text{NaN}$
- $\pm \text{inf} \odot \mp \text{inf} = \text{NaN}$
- $\pm \text{inf} = \pm \text{inf}$

## NaN behavior

- $\text{NaN} \odot a = \text{NaN}$
- $\text{NaN} \neq a$

# Floating-Point Undefined Behavior

- **Division by zero**

e.g.,  $10^8/0.0$

- **Conversion to a narrower floating-point type:**

e.g.,  $0.1$  double  $\rightarrow$  float

- **Conversion from floating-point to integer:**

e.g.,  $10^8$  float  $\rightarrow$  int

- **Operations on signaling NaNs:** Arithmetic operations that cause an “invalid operation” exception to be signaled

e.g.,  $\text{inf} - \text{inf}$

- **Incorrectly assuming IEEE-754 compliance for all platforms:**

e.g., Some embedded Linux distribution on ARM

C++11 allows determining if a floating-point exceptional condition has occurred by using floating-point exception facilities provided in `<cfenv>`

```
#include <cfenv>
// MACRO
FE_DIVBYZERO // division by zero
FE_INEXACT // rounding error
FE_INVALID // invalid operation, i.e. NaN
FE_OVERFLOW // overflow (reach saturation value +inf)
FE_UNDERFLOW // underflow (reach saturation value -inf)
FE_ALL_EXCEPT // all exceptions

// functions
std::feclearexcept(FE_ALL_EXCEPT); // clear exception status
std::fetestexcept(<macro>); // returns a value != 0 if an
                             // exception has been detected
```

# Detect Floating-point Errors ★

2/2

```
#include <cfenv>    // floating point exceptions
#include <iostream>
#pragma STDC FENV_ACCESS ON // tell the compiler to manipulate the floating-point
                           // environment (not supported by all compilers)
                           // gcc: yes, clang: no

int main() {
    std::feclearexcept(FE_ALL_EXCEPT); // clear
    auto x = 1.0 / 0.0;               // all compilers
    std::cout << (bool) std::fetestexcept(FE_DIVBYZERO); // print true

    std::feclearexcept(FE_ALL_EXCEPT); // clear
    auto x2 = 0.0 / 0.0;              // all compilers
    std::cout << (bool) std::fetestexcept(FE_INVALID); // print true

    std::feclearexcept(FE_ALL_EXCEPT); // clear
    auto x4 = 1e38f * 10;             // gcc: ok
    std::cout << std::fetestexcept(FE_OVERFLOW);        // print true
}
```

---

see What is the difference between quiet NaN and signaling NaN?

# Floating-point Issues

---

**Ariane 5:** data conversion from 64-bit floating point value to 16-bit signed integer → *\$137 million*

**Patriot Missile:** small chopping error at each operation, 100 hours activity → *28 deaths*

### Integer type is more accurate than floating type for large numbers

```
cout << 16777217;           // print 16777217
cout << (int) 16777217.0f; // print 16777216!!
cout << (int) 16777217.0;  // print 16777217, double ok
```

### float numbers are different from double numbers

```
cout << (1.1 != 1.1f); // print true !!!
```

## The floating point precision is finite!

```
cout << setprecision(20);
cout << 3.33333333f; // print 3.333333254!!
cout << 3.33333333; // print 3.33333333
cout << (0.1 + 0.1 + 0.1 + 0.1 + 0.1 + 0.1); // print 0.5999999999999998
```

## Floating point arithmetic is not associative

```
cout << 0.1 + (0.2 + 0.3) == (0.1 + 0.2) + 0.3; // print false
```

IEEE754 Floating-point computation guarantees to produce **deterministic** output, namely the exact bitwise value for each run, if and only if the order of the operations is always the same

→ *same result on any machine and for all runs*

*“Using a double-precision floating-point value, we can represent easily the number of atoms in the universe.*

*If your software ever produces a number so large that it will not fit in a double-precision floating-point value, chances are good that you have a bug”*

*Daniel Lemire, Prof. at the University of Quebec*

*“ NASA uses just 15 digits of  $\pi$  to calculate interplanetary travel.  
With 40 digits, you could calculate the circumference of a circle the size of the visible universe with an accuracy that would fall by less than the diameter of a single hydrogen atom”*

*Latest in space, Twitter*

# Floating-point Algorithms

- **addition algorithm** (simplified):

- (1) Compare the exponents of the two numbers. Shift the smaller number to the right until its exponent would match the larger exponent
- (2) Add the mantissa
- (3) Normalize the sum if needed (shift right/left the exponent by 1)

- **multiplication algorithm** (simplified):

- (1) Multiplication of mantissas. The number of bits of the result is twice the size of the operands (46 + 2 bits, with +2 for implicit normalization)
- (2) Normalize the product if needed (shift right/left the exponent by 1)
- (3) Addition of the exponents

- **fused multiply-add (fma)**:

- Recent architectures (also GPUs) provide `fma` to compute addition and multiplication in a single instruction (performed by the compiler in most cases)
- The rounding error of  $fma(x, y, z)$  is less than  $(x \otimes y) \oplus z$

## Catastrophic Cancellation

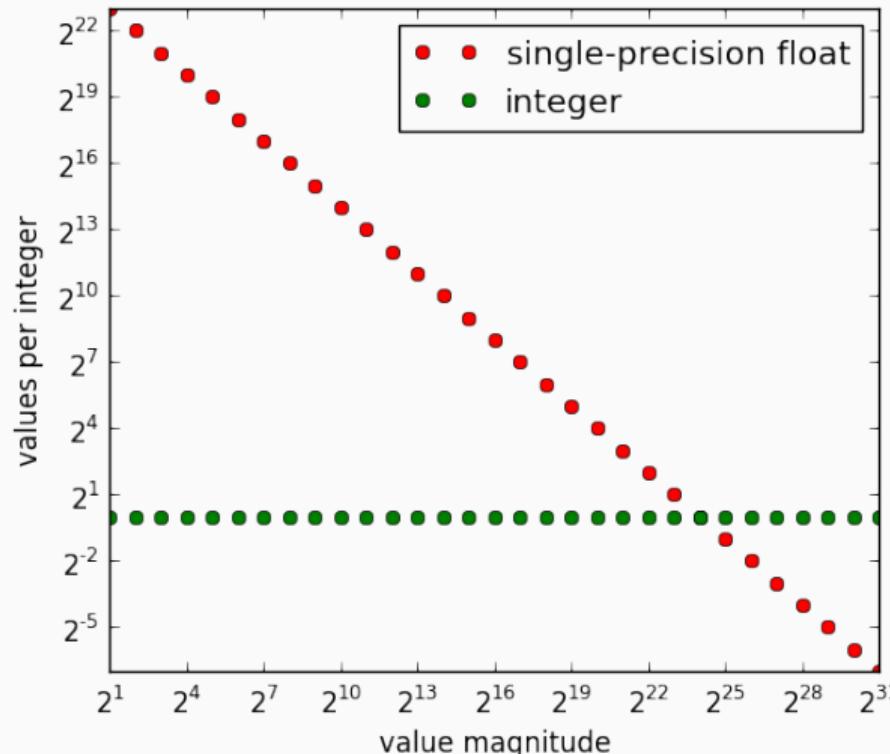

**Catastrophic cancellation** (or *loss of significance*) refers to loss of relevant information in a floating-point computation that cannot be recovered

Two cases:

- (C1)  $a \pm b$ , where  $a \gg b$  or  $b \gg a$ . The value (or part of the value) of the smaller number is lost
- (C2)  $a - b$ , where  $a, b$  are approximation of exact values and  $a \approx b$ , namely a loss of precision in both  $a$  and  $b$ .  $a - b$  cancels most of the relevant part of the result because  $a \approx b$ . It implies a *small absolute error* but a *large relative error*

## Catastrophic Cancellation (case 1) - Granularity

2/5

**Intersection** = 16,777,216 =  $2^{24}$

*How many iterations performs the following code?*

```
while (x > 0)  
    x = x - y;
```

How many iterations?

```
float:  x = 10,000,000      y = 1      -> 10,000,000  
float:  x = 30,000,000      y = 1      -> does not terminate  
float:  x =      200,000      y = 0.001 -> does not terminate  
bfloat: x =          256      y = 1      -> does not terminate !!
```

## Floating-point increment

```
float x = 0.0f;  
for (int i = 0; i < 20000000; i++)  
    x += 1.0f;
```

What is the value of `x` at the end of the loop?

---

Ceiling division  $\left\lceil \frac{a}{b} \right\rceil$

```
//           std::ceil((float) 101 / 2.0f) -> 50.5f -> 51  
float x = std::ceil((float) 20000001 / 2.0f);
```

What is the value of `x`?

Let's solve a quadratic equation:

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$x^2 + 5000x + 0.25$$

```
(-5000 + std::sqrt(5000.0f * 5000.0f - 4.0f * 1.0f * 0.25f)) / 2 // x2
(-5000 + std::sqrt(25000000.0f - 1.0f)) / 2 // catastrophic cancellation (C1)
(-5000 + std::sqrt(25000000.0f)) / 2
(-5000 + 5000) / 2 = 0                                // catastrophic cancellation (C2)
// correct result: 0.00005!!
```

relative error:  $\frac{|0 - 0.00005|}{0.00005} = 100\%$

## The problem

```
cout << (0.11f + 0.11f < 0.22f); // print true!!  
cout << (0.1f + 0.1f > 0.2f);    // print true!!
```

Do not use absolute error margins!!

```
bool areFloatNearlyEqual(float a, float b) {  
    if (std::abs(a - b) < epsilon); // epsilon is fixed by the user  
        return true;  
    return false;  
}
```

Problems:

- Fixed epsilon “looks small” but it could be too large when the numbers being compared are very small
- If the compared numbers are very large, the epsilon could end up being smaller than the smallest rounding error, so that the comparison always returns false

**Solution:** Use relative error  $\frac{|a-b|}{b} < \varepsilon$

```
bool areFloatNearlyEqual(float a, float b) {
    if (std::abs(a - b) / b < epsilon); // epsilon is fixed
        return true;
    return false;
}
```

Problems:

- **a=0, b=0** The division is evaluated as 0.0/0.0 and the whole if statement is (nan < epsilon) which always returns false
- **b=0** The division is evaluated as abs(a)/0.0 and the whole if statement is (+inf < epsilon) which always returns false
- **a and b very small.** The result should be true but the division by b may produce wrong results
- **It is not commutative.** We always divide by b

# Floating-point Comparison

Possible solution:  $\frac{|a-b|}{\max(|a|, |b|)} < \varepsilon$

```
bool areFloatNearlyEqual(float a, float b) {
    constexpr float normal_min      = std::numeric_limits<float>::min();
    constexpr float relative_error = <user_defined>

    if (!std::isfinite(a) || !isfinite(b)) // a = ±∞, NaN or b = ±∞, NaN
        return false;
    float diff   = std::abs(a - b);
    // if "a" and "b" are near to zero, the relative error is less effective
    if (diff <= normal_min) // or also: user_epsilon * normal_min
        return true;

    float abs_a = std::abs(a);
    float abs_b = std::abs(b);
    return (diff / std::max(abs_a, abs_b)) <= relative_error;
}
```

## Minimize Error Propagation - Summary

- Prefer **multiplication/division** rather than addition/subtraction
- Try to reorganize the computation to **keep near** numbers with the same scale (e.g. sorting numbers)
- Consider **putting a zero** very small number (under a threshold). Common application: iterative algorithms
- Scale by a **power of two** is safe
- **Switch to log scale.** Multiplication becomes Add, and Division becomes Subtraction
- Use a **compensation algorithm** like Kahan summation, Dekker's FastTwoSum, Rump's AccSum

# System/360 Model 44

Ken Shirriff: Want to adjust your computer's floating point precision by turning a knob? You could do that on the System/360 Model 44

# On Floating-Point

HEY, CHECK IT OUT:  $e^{\pi} - \pi$  IS 19.999099979. THAT'S WEIRD.

YEAH. THAT'S HOW I GOT KICKED OUT OF THE ACM IN COLLEGE.

... WHAT?

DURING A COMPETITION, I TOLD THE PROGRAMMERS ON OUR TEAM THAT  $e^{\pi} - \pi$  WAS A STANDARD TEST OF FLOATING-POINT HANDLERS -- IT WOULD COME OUT TO 20 UNLESS THEY HAD ROUNDING ERRORS.

THAT'S AWFUL.

YEAH, THEY DUG THROUGH HALF THEIR ALGORITHMS LOOKING FOR THE BUG BEFORE THEY FIGURED IT OUT.
