Table of Context

Table of Context

7 Integral Data Types

- Fixed Width Integers and size_t
- When Use Signed/Unsigned Integer?
- Promotion, Truncation
- Undefined Behavior

Preparation

What Compiler Should I Use?

Most popular compilers:

- Microsoft Visual Code (**MSVC**) is the compiler offered by Microsoft
- The GNU Compiler Collection (**GCC**) contains the most popular C++ Linux compiler
- **Clang** is a C++ compiler based on LLVM Infrastructure available for Linux/Windows/Apple (default) platforms

Suggested compiler on Linux for beginner: **Clang**

- Comparable performance with GCC/MSVC and low memory usage
- Expressive diagnostics (examples and propose corrections)
- Strict C++ compliance. GCC/MSVC compatibility (inverse direction is not ensured)
- Includes very useful tools: memory sanitizer, static code analyzer, automatic formatting, linter, etc.

Install the Compiler on Linux

Install the last gcc/g++ (v11) (v12 on Ubuntu 22.04)

```
$ sudo add-apt-repository ppa:ubuntu-toolchain-r/test
$ sudo apt update
$ sudo apt install gcc-11 g++-11
$ gcc-11 --version
```

Install the last clang/clang++ (v16)

```
$ bash -c "$(wget -O - https://apt.llvm.org/llvm.sh)"
$ wget https://apt.llvm.org/llvm.sh
$ chmod +x llvm.sh
$ sudo ./llvm.sh 16
$ clang++ --version
```

Install the Compiler on Windows

Microsoft Visual Studio

- Direct Installer: `Visual Studio Community 2022`

Clang on Windows

Two ways:

- Windows Subsystem for Linux (WSL)
    - `Run` → `optionalfeatures`
    - Select `Windows Subsystem for Linux`, `Hyper-V`, `Virtual Machine Platform`
    - `Run` → `ms-windows-store:` → Search and install `Ubuntu 22.04 LTS`
- Clang + MSVC Build Tools
    - Download Build Tools per Visual Studio
    - Install `Desktop development with C++`

Popular C++ IDE (Integrated Development Environment):

- **Microsoft Visual Studio** (MSVC) (link). Most popular IDE for Windows
- **Clion** (link). (free for student). Powerful IDE with a lot of options
- **QT-Creator** (link). Fast (written in C++), simple
- **XCode**. Default on Mac OS
- **Cevelop** (Eclipse) (link)

Standalone editors for coding (multi-platform):

- **Microsoft Visual Studio Code** (VSCode) (link)
- **Sublime Text editor** (link), written in C++
- **Vim**. Powerful, but needs expertise

Not suggested: Notepad, Gedit, and other similar editors (lack of support for programming) 8/100

How to Compile?

Compile C++11, C++14, C++17, C++20 programs:

```
g++  -std=c++11 <program.cpp> -o program
g++  -std=c++14 <program.cpp> -o program
g++  -std=c++17 <program.cpp> -o program
g++  -std=c++20 <program.cpp> -o program
```

Any C++ standard is backward compatible

C++ is also backward compatible with C, even for very old code, except if it contains C++ keywords (`new`, `template`, `class`, `typename`, etc.)

We can potentially compiles a pure C program in C++20

Compiler	C++11		C++14		C++17		C++20	
	Core	Library	Core	Library	Core	Library	Core	Library
g++	4.8.1	5.1	5.1	5.1	7.1	9.0	11+	11+
clang++	3.3	3.3	3.4	3.5	5.0	11.0	12+	14+
MSVC	19.0	19.0	19.10	19.0	19.15	19.15	19.29+	19.29

Meeting C++ Community Survey
Results for 2020 - Which C++ Standards do you currently use in your projects? (n=1030)
Hello World

C code with `printf` :

```c
#include <stdio.h>

int main() {
    printf("Hello World!\n");
}
```

`printf`
prints on standard output

C++ code with `streams` :

```cpp
#include <iostream>

int main() {
    std::cout << "Hello World!\n";
}
```

`cout`
represent the standard output stream

The previous example can be written with the global `std` namespace:

```cpp
#include <iostream>
using namespace std;

int main() {
    cout << "Hello World!\n";
}
```

Note: For sake of space and for improving the readability, we intentionally omit the `std` namespace in the next slides

`std::cout` is an example of *output* stream. Data is redirected to a destination, in this case the destination is the standard output

C:

```c
#include <stdio.h>
int main() {
    int    a  = 4;
    double b  = 3.0;
    char   c[] = "hello";
    printf("%d %f %s\n", a, b, c);
}
```

C++:

```cpp
#include <iostream>
int main() {
    int    a  = 4;
    double b  = 3.0;
    char   c[] = "hello";
    std::cout << a << " " << b << " " << c << "\n";
}
```

15/100

- **Type-safe**: The type of object provided to the I/O stream is known <u>statically</u> by the compiler. In contrast, `printf` uses `%` fields to figure out the types dynamically

- **Less error prone**: With IO Stream, there are no redundant `%` tokens that have to be consistent with the actual objects pass to I/O stream. Removing redundancy removes a class of errors

- **Extensible**: The C++ IO Stream mechanism allows new user-defined types to be pass to I/O stream without breaking existing code

- **Comparable performance**: If used correctly may be faster than C I/O (`printf` , `scanf` , etc.) .

16/100

- Forget the number of parameters:

```
printf("long phrase %d long phrase %d", 3);
```

- Use the wrong format:

```
int a = 3;
...many lines of code...
printf(" %f", a);
```

- The `%c` conversion specifier does not automatically skip any leading white space:

```
scanf("%d", &var1);
scanf(" %c", &var2);
```

Fundamental Types Overview

Arithmetic Types

Type	Bytes	Range	Fixed width types
`bool`	1	true, false	
`char` [†]	1	implementation defined	
`signed char`	1	-128 to 127	int8_t
`unsigned char`	1	0 to 255	uint8_t
`short`	2	-2^{15} to 2^{15}-1	int16_t
`unsigned short`	2	0 to 2^{16}-1	uint16_t
`int`	4	-2^{31} to 2^{31}-1	int32_t
`unsigned int`	4	0 to 2^{32}-1	uint32_t
`long int`	4/8[*]		int32_t/int64_t
`long unsigned int`	4/8[*]		uint32_t/uint64_t
`long long int`	8	-2^{63} to 2^{63}-1	int64_t
`long long unsigned int`	8	0 to 2^{64}-1	uint64_t
`float` (IEEE 754)	4	$\pm 1.18 \times 10^{-38}$ to $\pm 3.4 \times 10^{+38}$	
`double` (IEEE 754)	8	$\pm 2.23 \times 10^{-308}$ to $\pm 1.8 \times 10^{+308}$	

[*] 4 bytes on Windows64 systems, [†] `signed`/`unsigned`, two-complement from C++11

Arithmetic Types - Short Name

Signed Type	short name
signed char	/
signed short int	short
signed int	int
signed long int	long
signed long long int	long long

Unsigned Type	short name
unsigned char	/
unsigned short int	unsigned short
unsigned int	unsigned
unsigned long int	unsigned long
unsigned long long int	unsigned long long

Arithmetic Types - Suffix and Prefix

Type	SUFFIX	Example	Notes
`int`	/	2	
`unsigned int`	u, U	3u	
`long int`	l, L	8L	
`long unsigned`	ul, UL	2ul	
`long long int`	ll, LL	4ll	
`long long unsigned int`	ull, ULL	7ULL	
`float`	f, F	3.0f	only decimal numbers
`double`		3.0	only decimal numbers

Representation	PREFIX	Example
`Binary` C++14	0b	0b010101
`Octal`	0	0308
`Hexadecimal`	0x or 0X	0xFFA010

C++14 also allows *digit separators* for improving the readability `1'000'000`

Other Arithmetic Types

- C++ also provides `long double` (no IEEE-754) of size 8/12/16 bytes depending on the implementation

- C++23 starts to provide 16-bit floating-point data types IEEE 754–2008 `std::binary16` and `std::bfloat16`
  - Some compilers provide support for *half* (16-bit floating-point) (GCC for ARM: `__fp16`, LLVM compiler: `half`)
  - Some modern CPUs and GPUs provide *half* instructions
  - Software support: OpenGL, Photoshop, Lightroom, `half.sourceforge.net`

- C++ does not provide **128-bit integers** even if some architectures support it. `clang` and `gcc` allow 128-bit integers as compiler extension (`__int128`)

void **Type**

`void` is an incomplete type (not defined) without a value

- `void` indicates also a function with no return type or no parameters
  e.g. `void f()`, `f(void)`

- In C `sizeof(void) == 1` (GCC), while in C++ `sizeof(void)` does not
  compile!!

```
int main() {
// sizeof(void); // compile error
}
```

nullptr Keyword

C++11 introduces the new keyword `nullptr` to represent a null pointer (`0x0`) and replacing the `NULL` macro

```cpp
int* p1 = NULL;      // ok, equal to int* p1 = 0l
int* p2 = nullptr;   // ok, nullptr is a pointer not a number

int n1 = NULL;       // ok, we are assigning 0 to n1
// int n2 = nullptr; // compile error we are assigning
//                      a null pointer to an integer variable

// int* p2 = true ? 0 : nullptr; // compile error
//                                  // incompatible types
```

Remember: `nullptr` is not a pointer, but an object of type `nullptr_t` $\rightarrow$ safer

Fundamental Types Summary

The *fundamental types*, also called *primitive* or *built-in*, are organized into three main categories:

- Integers
- Floating-points
- `void` , `nullptr`

Any other entity in C++ is

- an *alias* to the correct type depending to the context and the architectures

- a *composition* of builtin types: struct/class, array, union

en.cppreference.com/w/cpp/types/integer
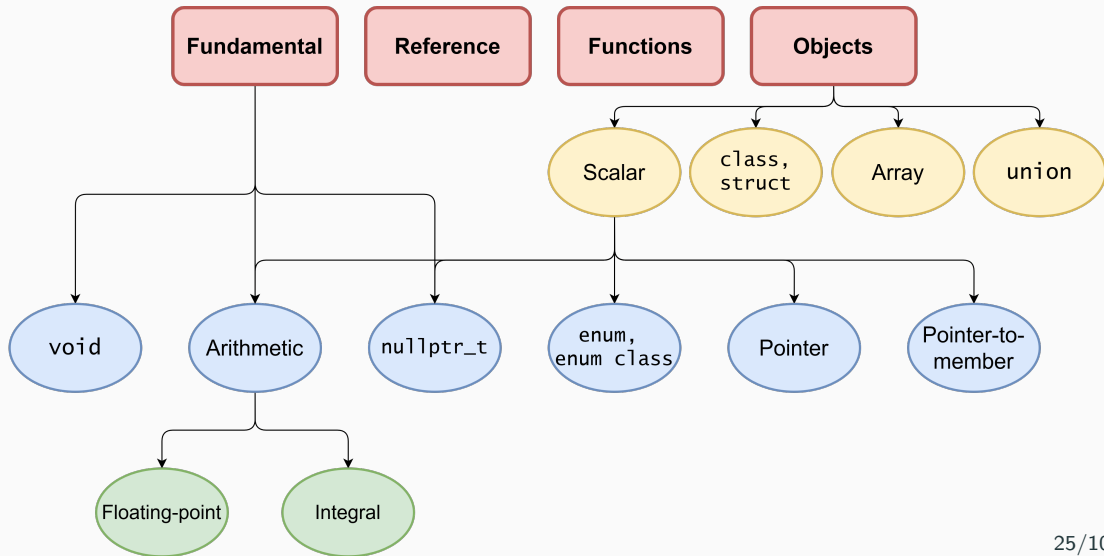

Conversion Rules

Conversion Rules

Implicit type conversion rules, applied <u>in order</u>, <u>before</u> any operation:

 $\otimes$: any operation (*, +, /, -, %, etc.)

(A) Floating point promotion

 `floating_type` $\otimes$ `integer_type` $\rightarrow$ `floating_type`

(B) Implicit integer promotion

 `small_integral_type` := any signed/unsigned integral type smaller than `int`

 `small_integral_type` $\otimes$ `small_integral_type` $\rightarrow$ `int`

(C) Size promotion

 `small_type` $\otimes$ `large_type` $\rightarrow$ `large_type`

(D) Sign promotion

 `signed_type` $\otimes$ `unsigned_type` $\rightarrow$ `unsigned_type`

Examples and Common Errors

```
float    f = 1.0f;
unsigned u = 2;
int      i = 3;
short    s = 4;
uint8_t  c = 5; // unsigned char

f * u; // float × unsigned → float: 2.0f
s * c; // short × unsigned char → int: 20
u * i; // unsigned × int → unsigned: 6u
+c;    // unsigned char → int: 5
```

Integers are not floating points!

```
int   b = 7;
float a = b / 2;   // a = 3 not 3.5!!
int   c = b / 2.0; // again c = 3 not 3.5!!
```

Implicit Promotion

Integral data types smaller than 32-bit are *implicitly* promoted to `int`, independently if they are *signed* or *unsigned*

- Unary `+, -, ~` and Binary `+, -, &, etc.` promotion:

```cpp
char a = 48;    // '0'
cout << a;      // print '0'
cout << +a;     // print '48'
cout << (a + 0); // print '48'

uint8_t a1 = 255;
uint8_t b1 = 255;
cout << (a1 + b1);  // print '510' (no overflow)
```

`auto` Declaration

C++11 The `auto` keyword specifies that the type of the variable will be automatically deduced by the compiler (from its initializer)

```
auto a = 1 + 2;   // 1 is int, 2 is int, 1 + 2 is int!
//    -> 'a' is "int"
auto b = 1 + 2.0; // 1 is int, 2.0 is double. 1 + 2.0 is double
//    -> 'b' is "double"
```

`auto` can be very useful for maintainability and for hiding complex type definitions

```
for (auto i = k; i < size; i++)
    ...
```

On the other hand, it may make the code less readable if excessively used because of type hiding

Example: `auto x = 0;` in general makes no sense (`x` is `int`)

`auto` (as well as `decltype`) can be used for defining both function input C++20 and output types C++11/C++14

```cpp
auto g(int x) -> int { return x * 2; } // C++11
// "-> int" is the deduction type
// a better way to express it is:
auto g2(int x) -> decltype(x * 2) { return x * 2; }

auto h(int x) { return x * 2; }        // C++14

void f(auto x) {}                      // C++20
// equivalent to templates but less expensive at compile-time
//------------------------------------------------------------
int x = g(3); // C++11

f(3);        // C++20
f(3.0);      // C++20
```

C++ Operators

Precedence	Operator	Description	Associativity
1	a++ a--	Suffix/postfix increment and decrement	Left-to-right
2	++a --a ! $\sim$	Prefix increment/decrement, Logical/Bitwise Not	Right-to-left
3	a*b a/b a%b	Multiplication, division, and remainder	Left-to-right
4	a+b a-b	Addition and subtraction	Left-to-right
5	$\ll$ $\gg$	Bitwise left shift and right shift	Left-to-right
6	< <= > >=	Relational operators	Left-to-right
7	== !=	Equality operators	Left-to-right
8	&	Bitwise AND	Left-to-right
9	^	Bitwise XOR	Left-to-right
10			Bitwise OR	Left-to-right
11	&&	Logical AND	Left-to-right
12	||	Logical OR	Left-to-right

- **Unary** operators have <u>higher</u> precedence than **binary operators**

- **Standard math operators** (`+`, `*`, etc.) have <u>higher</u> precedence than **comparison**, **bitwise**, and **logic** operators

- **Comparison** operators have <u>higher</u> precedence than **bitwise** and **logic operators**

- **Bitwise** operators have <u>higher</u> precedence than **logic** operators

- **Compound assignment** operators `+=` , `-=` , `*=` , `/=` , `%=` , `^=` , `!=` , `&=` , `>>=` , `<<=` have <u>lower</u> priority

- The **comma** operator has the <u>lowest</u> precedence (see next slides)

en.cppreference.com/w/cpp/language/operator_precedence

Examples:

```
a + b * 4;          // a + (b * 4)

a * b / c % d;      // ((a * b) / c) % d

a + b < 3 >> 4;     // (a + b) < (3 >> 4)

a && b && c || d;   // (a && b && c) || d

a | b & c || e && d; // ((a | (b & c)) || (e && d)
```

Important: sometimes parenthesis can make expression worldly... but they can help!

Prefix/Postfix Increment Semantic

Prefix Increment/Decrement `++i` , `--i`

(1) Update the value

(2) Return the new (updated) value

Postfix Increment/Decrement `i++` , `i--`

(1) Save the old value (temporary)

(2) Update the value

(3) Return the old (original) value

Prefix/Postfix increment/decrement semantic applies not only to built-in types but also to objects

Operation Ordering Undefined Behavior ⋆

Expressions with undefined (implementation-defined) behavior:

```cpp
int i = 0;
i = ++i + 2;      // until C++11: undefined behavior
                  // since C++11:  i = 3
i = 0;
i = i++ + 2;      // until C++17: undefined behavior
                  // since C++17: i = 3

f(i = 2, i = 1);  // until C++17: undefined behavior
                  // since C++17:  i = 2
i = 0;
a[i] = i++;       // until C++17: undefined behavior
                  // since C++17: a[1] = 1

f(++i, ++i);      // undefined behavior
i = ++i + i++;    // undefined behavior
```

Assignment, Compound, and Comma Operators

Assignment and **compound assignment** operators have *right-to-left associativity* and their expressions return the assigned value

```
int y = 2;
int x = y = 3; // y=3, then x=3
               // the same of x = (y = 3)
if (x = 4)     // assign x=4 and evaluate to true
```

The **comma** operator has *left-to-right associativity*. It evaluates the left expression, discards its result, and returns the right expression

```
int a = 5, b = 7;
int x = (3, 4); // discards 3, then x=4
int y = 0;
int z;
z = y, x;       // z=y (0), then returns x (4)
```

Spaceship Operator <=>

C++20 provides the **three-way comparison operator** `<=>`, also called *spaceship operator*, which allows comparing two objects in a similar way of `strcmp`. The operator returns an object that can be directly compared with a positive, 0, or negative integer value

```
(3 <=> 5)     == 0; // false
('a' <=> 'a') == 0; // true

(3 <=> 5)      < 0; // true
(7 <=> 5)      < 0; // false
```

The semantic of the *spaceship operator* can be extended to any object (see next lectures) and can greatly simplify the comparison operators overloading

Safe Comparison Operators

C++20 introduces a set of functions `<utility>` to safely compare integers of different types (signed, unsigned)

```
bool cmp_equal(T1 a, T2 b)
bool cmp_not_equal(T1 a, T2 b)
bool cmp_less(T1 a, T2 b)
bool cmp_greater(T1 a, T2 b)
bool cmp_less_equal(T1 a, T2 b)
bool cmp_greater_equal(T1 a, T2 b)
```

example:

```
#include <utility>
unsigned a  = 4;
int      b  = -3;
bool     v1 = (a > b);            // false!!!, see next slides
bool     v2 = cmp_greater(a, b); // true
```

Integral Data Types

A Firmware Bug

"Certain SSDs have a firmware bug causing them to irrecoverably fail after exactly 32,768 hours of operation. SSDs that were put into service at the same time will fail simultaneously, so RAID won't help"

`HPE SAS Solid State Drives - Critical Firmware Upgrade`

Overflow Implementations

Mergesorts are Broken

Friday, June 2, 2006

Posted by Joshua Bloch, Software Engineer

Note: Computing the average in the right way is not trivial, see `On finding the average of two unsigned integers without overflow`

related operations: ceiling division, rounding division

$$51 \; days = 51 \cdot 24 \cdot 60 \cdot 60 \cdot 1000 = 4\,406\,400\,000 \; ms$$

Boeing 787s must be turned off and on every 51 days to prevent 'misleading data' being shown to pilots

C++ Data Model

LP32   Windows 16-bit APIs (no more used)
ILP32   Windows 32-bit APIs, Unix 32-bit (Linux, Mac OS)
LLP64   Windows 64-bit APIs
LP64   Linux 64-bit APIs

Model/Bits	short	int	long	long long	pointer
ILP32	16	32	32	64	32
LLP64	16	32	32	64	64
LP64	16	32	64	64	64

`char` is always 1 byte

C++ Fundamental types

int*_t <cstdint>

C++ provides fixed width integer types.
They have the same size on any architecture:

int8_t, uint8_t
int16_t, uint16_t
int32_t, uint32_t
int64_t, uint64_t

Good practice: Prefer fixed-width integers instead of native types. `int` and
`unsigned` can be directly used as they are widely accepted by C++ data models

`int*_t` types are <u>not</u> "real" types, they are merely *typedefs* to appropriate fundamental types

C++ standard does not ensure a one-to-one mapping:

- There are **five** distinct *fundamental types* (`char` , `short` , `int` , `long` , `long long`)

- There are **four** `int*_t` *overloads* (`int8_t` , `int16_t` , `int32_t` , and `int64_t`)

Warning: I/O Stream interprets `uint8_t` and `int8_t` as `char` and not as integer values

```
int8_t var;
cin >> var;  // read '2'
cout << var; // print '2'
int a = var * 2;
cout << a;   // print '100' !!
```

size_t

size_t <cstddef>

size_t is an *alias* data type capable of storing the biggest representable value on the current architecture

- size_t is an <u>unsigned integer</u> type (of at least 16-bit)
- In common C++ implementations:
    - size_t is 4 bytes on 32-bit architectures
    - size_t is 8 bytes on 64-bit architectures
- size_t is commonly used to represent size measures

Signed and unsigned integers use the same hardware for their operations, but they have very different semantic:

signed integers

- Represent positive, negative, and zero values ($\mathbb{Z}$)

- More negative values ($2^{31} - 1$) than positive ($2^{31} - 2$)

- Overflow/underflow is undefined behavior
  Possible behavior:
    overflow: $(2^{31} - 1) + 1 \rightarrow min$
    underflow: $-2^{31} - 1 \rightarrow max$

- Bit-wise operations are implementation-defined

- Commutative, reflexive, not associative (overflow/underflow)

unsigned integers

- Represent only *non-negative* values ($\mathbb{N}$)

- Overflow/underflow is <u>well-defined</u> (modulo 2^{32})

- Discontinuity in 0, $2^{32} - 1$

- Bit-wise operations are <u>well-defined</u>

- Commutative, reflexive, associative

Google Style Guide

> Because of historical accident, the C++ standard also uses unsigned integers to represent the size of containers - many members of the standards body believe this to be a mistake, but it is effectively impossible to fix at this point

Solution: use `int64_t`

max value: $2^{63} - 1 = $ 9,223,372,036,854,775,807 or
9 quintillion (9 billion of billion),
about 292 years (nanoseconds),
9 million terabytes

```
Subscripts and sizes should be signed, WG21 P1428R0, Bjarne Stroustrup
Don't add to the signed/unsigned mess, WG21 P1491R0, Bjarne Stroustrup
```

Arithmetic Type Limits

Query properties of arithmetic types in C++11:

```cpp
#include <limits>

std::numeric_limits<int>::max();      // 2^31 - 1
std::numeric_limits<uint16_t>::max(); // 65,535

std::numeric_limits<int>::min();      // -2^31
std::numeric_limits<unsigned>::min(); // 0
```

* this syntax will be explained in the next lectures

Promotion and Truncation

Promotion to a larger type keeps the sign

```
int16_t x = -1;
int     y = x; // sign extend
cout << y;     // print -1
```

Truncation to a smaller type is implemented as a modulo operation with respect to the number of bits of the smaller type

```
int     x = 65537; // 2^16 + 1
int16_t y = x;     // x % 2^16
cout << y;         // print 1

int     z = 32769; // 2^15 + 1 (does not fit in a int16_t)
int16_t w = z;     // (int16_t) (x % 2^16 = 32769)
cout << w;         // print -32767
```

```
unsigned a = 10;  // array is small
int      b = -1;
array[10ull + a * b] = 0; // ?
```

☠ Segmentation fault!

```
int f(int a, unsigned b, int* array) {  // array is small
    if (a > b)
        return array[a - b]; // ?
    return 0;
}
```

☠ Segmentation fault for "a" ¡ 0!

```
// v.size() return unsigned
for (size_t i = 0; i < v.size() - 1; i++)
    array[i] = 3; // ?
```

☠ Segmentation fault for v.size() = 0!

Easy case:

```
unsigned x = 32;      // x can be also a pointer
x        += 2u - 4;   // 2u - 4 = 2 + (2^32 - 4)
                      //        = 2^32 - 2
                      // (32 + (2^32 - 2)) % 2^32
cout << x;            // print 30 (as expected)
```

What about the following code?

```
uint64_t x = 32;      // x can be also a pointer
x        += 2u - 4;
cout << x;
```

More negative values than positive

```
int x = std::numeric_limits<int>::max() * -1; // (2^31 -1) * -1
cout << x;                                     // -2^31 +1 ok

int y = std::numeric_limits<int>::min() * -1; // -2^31 * -1
cout << y; // hard to see in complex examples // 2^31 overflow!!
```

A pratical example:

```
void f(int* ptr, int pos) {
    pos++;
    if (pos < 0)
        return;      // <-- the compiler assumes that
    ptr[pos] = 0;    //     signed overflow never happen
}                    //     and removes the if statement
int main() {         // compiled with optimizations
    int tmp[10];     // leads to segmentation faults
    f(tmp, INT_MAX);
}
```

54/100

Initialize an integer with a value larger then its range is undefined behavior

```
int z = 3000000000; // undefined behavior!!
```

Bitwise operations on signed integer types is undefined behavior

```
int y = 1 << 12;    // undefined behavior!!
```

Shift larger than #bits of the data type is undefined behavior even for **unsigned**

```
unsigned y = 1u << 32u; // undefined behavior!!
```

Undefined behavior in implicit conversion

```
uint16_t a = 65535; // 0xFFFF
uint16_t b = 65535; // 0xFFFF                    expected: 4'294'836'225
cout << (a * b);    // print '-131071' undefined behavior!! (int overflow)
```

The Usual Arithmetic Confusions

Even worse example:

```
#include <iostream>

int main() {
    for (int i = 0; i < 4; ++i)
        std::cout << i * 1000000000 << std::endl;
}
// with optimizations, it is an infinite loop
// --> 1000000000 * i > INT_MAX
// undefined behavior!!

// the compiler translates the multiplication constant into an addition
```

Why does this loop produce undefined behavior?

Is the following loop safe?

```
void f(int size) {
    for (int i = 1; i < size; i += 2)
        ...
}
```

- What happens if `size` is equal to `INT_MAX` ?
- How to make the previous loop safe?
- `i >= 0 && i < size` is not the solution because of *undefined behavior* of signed overflow
- Can we generalize the solution when the increment is `i += step` ?

Overflow / Underflow

Detecting overflow/underflow for <u>unsigned integral</u> types is **not trivial**

```cpp
// some examples
bool is_add_overflow(unsigned a, unsigned b) {
    return (a + b) < a || (a + b) < b;
}

bool is_mul_overflow(unsigned a, unsigned b) {
    unsigned x = a * b;
    return a != 0 && (x / a) != b;
}
```

Overflow/underflow for <u>signed integral</u> types is **not defined** !! *Undefined behavior* must be checked <u>before</u> performing the operation

Floating-point Types and Arithmetic

32/64-bit Floating-Point

IEEE754 is the technical standard for floating-point arithmetic

The standard defines the binary format, operations behavior, rounding rules, exception handling, etc.

- First Release: 1985
- Second Release: 2008. Add 16-bit floating point
- Third Release: 2019. Specify min/max behavior

see The IEEE Standard 754: One for the History Books

IEEE764 technical document:

754-2019 - IEEE Standard for Floating-Point Arithmetic

In general, **C/C++ adopts IEEE754 floating-point standard**:

en.cppreference.com/w/cpp/types/numeric_limits/is_iec559

## 32/64-bit Floating-Point

- **IEEE764 Single precision** (32-bit) `float`

Sign	Exponent (or base)	Mantissa (or significant)
1-bit	8-bit	23-bit
- **IEEE764 Double precision** (64-bit) `double`

Sign	Exponent (or base)	Mantissa (or significant)
1-bit	11-bit	52-bit
16-bit Floating-Point (Standardized in C++23)

- **IEEE754 16-bit Floating-point** (`std::binary16`) $\rightarrow$, GPU, Arm7

Sign 1-bit	Exponent 5-bit	Mantissa 10-bit

- **Google 16-bit Floating-point** (`std::bfloat16`) $\rightarrow$, TPU, GPU, Arm8

Sign 1-bit	Exponent 8-bit	Mantissa 7-bit

half-precision-arithmetic-fp16-versus-bfloat16
8-bit Floating-Point (Non-Standardized in C++)

- `E4M3`

Sign 1-bit	Exponent 4-bit	Mantissa 3-bit

- `E5M2`

Sign 1-bit	Exponent 5-bit	Mantissa 2-bit
Other Real Value Representations (Non-standardized in C++)

- **TensorFloat-32 (TF32)** Specialized floating-point format for deep learning applications

- **Posit** (John Gustafson, 2017), also called *unum III* (*universal number*), represents floating-point values with *variable-width* of exponent and mantissa. It is implemented in experimental platforms

- **Fixed-point** representation has a fixed number of digits after the radix point (decimal point). The gaps between adjacent numbers are always equal. The range of their values is significantly limited compared to floating-point numbers. It is widely used on embedded systems

---

- NVIDIA Hopper Architecture In-Depth
- Beating Floating Point at its Own Game: Posit Arithmetic
- Comparing posit and IEEE-754 hardware cost

Floating-point number:

- *Radix* (or base): β
- *Precision* (or digits): p
- *Exponent* (magnitude): e
- *Mantissa*: M

$$n = \underbrace{M}_{p} \times \beta^{e} \quad \rightarrow \quad \text{IEEE754: } 1.M \times 2^{e}$$

```
float  f1 = 1.3f;   // 1.3
float  f2 = 1.1e2f; // 1.1 · 10²
float  f3 = 3.7E4f; // 3.7 · 10⁴
float  f4 = .3f;    // 0.3
double d1 = 1.3;    // without "f"
double d2 = 5E3;    // 5 · 10³
```

Exponent Bias

In IEEE754 floating point numbers, the exponent value is offset from the actual value by the **exponent bias**

- The exponent is stored as an unsigned value suitable for comparison

- Floating point values are lexicographic ordered

- For a single-precision number, the exponent is stored in the range $[1, 254]$ (0 and 255 have special meanings), and is biased by subtracting 127 to get an exponent value in the range $[-126, +127]$

0	10000111	11000000000000000000000
+	$2^{(135-127)} = 2^8$	$\frac{1}{2^1} + \frac{1}{2^2} = 0.5 + 0.25 = 0.75 \overset{normal}{\rightarrow} 1.75$

$$+1.75 * 2^8 = 448.0$$

Normal number

A **normal** number is a floating point value that can be represented with *at least one bit set in the exponent* or the mantissa has all 0s
Denormal number

Denormal (or subnormal) numbers fill the underflow gap around zero in floating-point arithmetic. Any non-zero number with magnitude smaller than the smallest normal number is denormal

A **denormal** number is a floating point value that can be represented with *all 0s in the exponent*, but the mantissa is non-zero
Why denormal numbers make sense: (↓ normal numbers)

The problem: distance values from zero   (↓ denormal numbers)

Infinity

In the IEEE754 standard, `inf` (infinity value) is a numeric data type value that exceeds the maximum (or minimum) representable value

Operations generating `inf` :

- $\pm\infty \cdot \pm\infty$
- $\pm\infty \cdot \pm\text{finite\_value}$
- finite_value *op* finite_value $>$ max_value
- non-NaN $/ \pm 0$

There is a single representation for +inf and -inf

Comparison: (inf == finite_value) $\rightarrow$ false

$(\pm\text{inf} == \pm\text{inf}) \qquad \rightarrow$ true

```
cout << 0 / 0;        // undefined behavior
cout << 0.0 / 0.0;    // print "nan"
cout << 5.0 / 0.0;    // print "inf"
cout << -5.0 / 0.0;   // print "-inf"

auto inf = std::numeric_limits<float>::infinity;
cout << (-0.0 == 0.0);                        // true, 0 == 0
cout << ((5.0f / inf) == ((-5.0f / inf));     // true, 0 == 0
cout << (10e40f) == (10e40f + 9999999.0f);    // true, inf == inf
cout << (10e40)  == (10e40f + 9999999.0f);    // false, 10e40 != inf
```

Not a Number (NaN)

NaN

In the IEEE754 standard, `NaN` (not a number) is a numeric data type value representing an undefined or unrepresentable value

Operations generating `NaN` :

- Operations with a `NaN` as at least one operand
- $\pm\infty \cdot \mp\infty$, $0 \cdot \infty$
- $0/0, \infty/\infty$
- $\sqrt{x}$, $\log(x)$ for $x < 0$
- $\sin^{-1}(x), \cos^{-1}(x)$ for $x < -1$ or $x > 1$

There are many representations for `NaN` (e.g. $2^{24} - 2$ for `float`)

Comparison: (NaN == x) $\rightarrow$ false, for every x

(NaN == NaN) $\rightarrow$ false

Machine Epsilon

Machine epsilon

Machine epsilon ε (or *machine accuracy*) is defined to be the smallest number that can be added to 1.0 to give a number other than one

IEEE 754 Single precision : $\varepsilon = 2^{-23} \approx 1.19209 * 10^{-7}$

IEEE 754 Double precision : $\varepsilon = 2^{-52} \approx 2.22045 * 10^{-16}$

Units at the Last Place

ULP

Units at the Last Place is the gap between consecutive floating-point numbers
$$ULP(p, e) = 1.0 \times \beta^{e-(p-1)}$$

Example:

$\beta = 10, \ p = 3$

$\pi = 3.1415926... \rightarrow x = 3.14 \times 10^0$

$ULP(3, 0) = 10^{-2} = 0.01$

Relation with ε:

- $\varepsilon = ULP(p, 0)$
- $ULP_x = \varepsilon * \beta^{e(x)}$

Floating-point Error

Machine floating-point representation of x is denoted **fl(x)**

$fl(x) = x(1 + \delta)$

Absolute Error: $|fl(x) - x| \leq \frac{1}{2} \cdot ULP_x$

Relative Error: $\left| \frac{fl(x) - x}{x} \right| \leq \frac{1}{2} \cdot \varepsilon$

- NaN (mantissa $\neq 0$)

Floating-point - Limits

```cpp
#include <limits>
// T: float or double

std::numeric_limits<T>::max();       // largest value

std::numeric_limits<T>::lowest();    // lowest value (C++11)

std::numeric_limits<T>::min();       // smallest value

std::numeric_limits<T>::denorm_min() // smallest (denormal) value

std::numeric_limits<T>::epsilon();   // epsilon value

std::numeric_limits<T>::infinity()   // infinity

std::numeric_limits<T>::quiet_NaN()  // NaN
```

Floating-point - Useful Functions

```cpp
#include <cmath> // C++11

bool std::isnan(T value)     // check if value is NaN
bool std::isinf(T value)     // check if value is ±infinity
bool std::isfinite(T value)  // check if value is not NaN
                             // and not ±infinity

bool std::isnormal(T value); // check if value is Normal

T   std::ldexp(T x, p)       // exponent shift x * 2^p
int std::ilogb(T value)      // extracts the exponent of value
```

Floating-point operations are written

- $\oplus$ addition
- $\ominus$ subtraction
- $\otimes$ multiplication
- $\oslash$ division

$\odot \in \{\oplus, \ominus, \otimes, \oslash\}$

$op \in \{+, -, *, \backslash\}$ denotes exact precision operations

(P1) In general, a *op* $b \neq a \odot b$

(P2) **Not Reflexive** $a \neq a$
   - *Reflexive* without NaN

(P3) **Not Commutative** $a \odot b \neq b \odot a$
   - *Commutative* without NaN (NaN $\neq$ NaN)

(P4) In general, **Not Associative** $(a \odot b) \odot c \neq a \odot (b \odot c)$

(P5) In general, **Not Distributive** $(a \oplus b) \otimes c \neq (a \cdot c) \oplus (b \cdot c)$

(P6) **Identity on operations is not ensured** $(k \oslash a) \otimes a \neq k$

(P7) **No overflow/underflow** Floating-point has *"saturation"* values inf, -inf
   - Adding (or subtracting) can "saturate" before inf, -inf

C++11 allows determining if a floating-point exceptional condition has occurred by using floating-point exception facilities provided in `<cfenv>`

```cpp
#include <cfenv>
// MACRO
FE_DIVBYZERO  // division by zero
FE_INEXACT    // rounding error
FE_INVALID    // invalid operation, i.e. NaN
FE_OVERFLOW   // overflow (reach saturation value +inf)
FE_UNDERFLOW  // underflow  (reach saturation value -inf)
FE_ALL_EXCEPT // all exceptions

// functions
std::feclearexcept(FE_ALL_EXCEPT); // clear exception status
std::fetestexcept(<macro>);        // returns a value != 0 if an
                                   // exception has been detected
```

```cpp
#include <cfenv>     // floating point exceptions
#include <iostream>
#pragma STDC FENV_ACCESS ON // tell the compiler to manipulate the floating-point
                            // environment (not supported by all compilers)
                            // gcc: yes, clang: no
int main() {
    std::feclearexcept(FE_ALL_EXCEPT); // clear
    auto x = 1.0 / 0.0;                // all compilers
    std::cout << (bool) std::fetestexcept(FE_DIVBYZERO); // print true

    std::feclearexcept(FE_ALL_EXCEPT); // clear
    auto x2 = 0.0 / 0.0;               // all compilers
    std::cout << (bool)  std::fetestexcept(FE_INVALID);  // print true

    std::feclearexcept(FE_ALL_EXCEPT); // clear
    auto x4 = 1e38f * 10;              // gcc: ok
    std::cout << std::fetestexcept(FE_OVERFLOW);         // print true
}
```

see What is the difference between quiet NaN and signaling NaN?

Floating-point Issues

Ariene 5: data conversion from 64-bit floating point value to 16-bit signed integer → *$137 million*

Patriot Missile: small chopping error at each operation, 100 hours activity → *28 deaths*

Integer type is more accurate than floating type for large numbers

```
cout << 16777217;         // print 16777217
cout << (int) 16777217.0f; // print 16777216!!
cout << (int) 16777217.0;  // print 16777217, double ok
```

float numbers are different from double numbers

```
cout << (1.1 != 1.1f); // print true !!!
```

The floating point precision is finite!

```
cout << setprecision(20);
cout << 3.33333333f; // print 3.333333254!!
cout << 3.33333333; // print 3.333333333
cout << (0.1 + 0.1 + 0.1 + 0.1 + 0.1 + 0.1); // print 0.59999999999999998
```

Floating point arithmetic is not associative

```
cout << 0.1 + (0.2 + 0.3) == (0.1 + 0.2) + 0.3; // print false
```

IEEE764 Floating-point computation guarantees to produce **deterministic** output, namely the exact bitwise value for each run, if and only if the **order of the operations is always the same**

$\rightarrow$ *same result on any machine and for all runs*

"Using a double-precision floating-point value, we can represent easily the number of atoms in the universe.

If your software ever produces a number so large that it will not fit in a double-precision floating-point value, chances are good that you have a bug"

Daniel Lemire, Prof. at the University of Quebec

" NASA uses just 15 digits of π to calculate interplanetary travel.
With 40 digits, you could calculate the circumference of a circle the size of the visible universe with an accuracy that would fall by less than the diameter of a single hydrogen atom"

Latest in space, Twitter

Number of atoms in the universe versus floating-point values

Floating-point Algorithms

- **addition algorithm** (simplified):
  1. Compare the exponents of the two numbers. Shift the smaller number to the right until its exponent would match the larger exponent
  2. Add the mantissa
  3. Normalize the sum if needed (shift right/left the exponent)

- **multiplication algorithm** (simplified):
  1. Multiplication of mantissas. The number of bits of the result is twice the size of the operands (46 + 2 bits, +2 for implicit normalization)
  2. Normalize the product if needed (shift right/left the exponent)
  3. Addition of the exponents

- **fused multiply-add** (fma):
  - Recent architectures (also GPUs) provide fma to compute these two operations in a single instruction (performed by the compiler in most cases)
 - The rounding error is lower $fl(fma(x, y, z)) < fl((x \otimes y) \oplus z)$

Catastrophic Cancellation

Catastrophic Cancellation

Catastrophic cancellation (or *loss of significance*) refers to loss of relevant information in a floating-point computation that cannot be revered

Two cases:

(C1) $a \pm b$, where $a \gg b$ or $b \gg a$. The value (or part of the value) of the smaller number is lost

(C2) $a - b$, where a, b are approximation of exact values and $a \approx b$, namely a loss of precision in both a and b. $a - b$ cancels most of the relevant part of the result because $a \approx b$. It implies a *small absolute error* but a *large relative error*
Intersection $= 16,777,216 = 2^{24}$

How many iterations performs the following code?

```
while (x > 0)
    x = x - y;
```

How many iterations?

```
float:  x = 10,000,000  y = 1     -> 10,000,000
float:  x = 30,000,000  y = 1     -> does not terminate
float:  x =    200,000  y = 0.001 -> does not terminate
bfloat: x =        256  y = 1     -> does not terminate !!
```

Floating-point increment

```
float x = 0.0f;
for (int i = 0; i < 20000000; i++)
x += 1.0f;
```

What is the value of x at the end of the loop?

Ceiling division $\left\lceil \dfrac{a}{b} \right\rceil$

```
//         std::ceil((float) 101 / 2.0f) -> 50.5f -> 51
float x = std::ceil((float) 20000001 / 2.0f);
```

What is the value of x ?

Catastrophic Cancellation (case 2)

Let's solve a quadratic equation:

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$x^2 + 5000x + 0.25$

```
(-5000 + std::sqrt(5000.0f * 5000.0f - 4.0f * 1.0f * 0.25f)) / 2 // x2
(-5000 + std::sqrt(25000000.0f - 1.0f)) / 2 // catastrophic cancellation (C1)
(-5000 + std::sqrt(25000000.0f)) / 2
(-5000 + 5000) / 2 = 0                        // catastrophic cancellation (C2)
// correct result: 0.00005!!
```

relative error: $\frac{|0 - 0.00005|}{0.00005} = 100\%$

The problem

```cpp
cout << (0.11f + 0.11f < 0.22f); // print true!!
cout << (0.1f + 0.1f > 0.2f);    // print true!!
```

Do not use absolute error margins!!

```cpp
bool areFloatNearlyEqual(float a, float b) {
    if (std::abs(a - b) < epsilon); // epsilon is fixed by the user
        return true;
    return false;
}
```

Problems:

- Fixed epsilon "looks small" but it could be too large when the numbers being compared are very small
- If the compared numbers are very large, the epsilon could end up being smaller than the smallest rounding error, so that the comparison always returns false

Solution: Use relative error $\quad \frac{|a-b|}{b} < \varepsilon$

```cpp
bool areFloatNearlyEqual(float a, float b) {
    if (std::abs(a - b) / b < epsilon); // epsilon is fixed
        return true;
    return false;
}
```

Problems:

- `a=0, b=0` The division is evaluated as 0.0/0.0 and the whole if statement is (nan < espilon) which always returns false

- `b=0` The division is evaluated as abs(a)/0.0 and the whole if statement is (+inf < espilon) which always returns false

- **a and b very small.** The result should be true but the division by b may produces wrong results

- **It is not commutative.** We always divide by b

Possible solution: $\frac{|a-b|}{\max(|a|,|b|)} < \varepsilon$

```cpp
bool areFloatNearlyEqual(float a, float b) {
    const float normal_min    = std::numeric_limits<float>::min();
    const float relative_error = <user_defined>

    if (!std::isfinite(a) || !isfinite(b)) // a = ±∞, NaN or b = ±∞, NaN
        return false;
    float diff = std::abs(a - b);
    // if "a" and "b" are near to zero, the relative error is less effective
    if (diff <= normal_min) // or also: user_epsilon *  normal_min
        return true;

    float abs_a = std::abs(a);
    float abs_b = std::abs(b);
    return (diff / std::max(abs_a, abs_b)) <= relative_error;
}
```

Minimize Error Propagation - Summary

- Prefer **multiplication/division** rather than addition/subtraction

- Try to reorganize the computation to **keep near** numbers with the same scale (e.g. sorting numbers)

- Consider to **put a zero** very small number (under a threshold). Common application: iterative algorithms

- Scale by a **power of two** is safe

- **Switch to log scale**. Multiplication becomes Add, and Division becomes Subtraction

- Use a **compensation algorithm** like Kahan summation, Dekker's FastTwoSum, Rump's AccSum
